

ThesisTrack

A Python-Based Investment Decision Quality Analyzer

**Can a profitable investment still
come from an inaccurate forecast?**

Beyond “Did the Stock Make Money?”

I built ThesisTrack to evaluate the quality of an investment decision — not just its final return.

Did the Forecast Match Reality?

All six forecasts got the direction right — but the magnitude of the returns varied considerably.

Getting the Direction Right ≠ Getting the Forecast Right

ANALYTICAL INSIGHT

Most accurate:
AAPL — 0.09 pp

Largest miss:
JPM — 24.57 pp

**Potential
overconfidence flag:**

Average Forecast Error

1

Potential Overconfidence Case

A profitable outcome does not automatically mean the original forecast was accurate.

→ Strongest thesis by return: Value (+36.57%)

From Learning Python to Applying It in Finance

I wanted to move beyond learning Python concepts and apply them to a real financial decision-making problem.

ThesisTrack became my first end-to-end Python finance project - from designing the logic to analysing investment outcomes.

What ThesisTrack Taught Me

01

Outcome != Decision Quality

A profitable investment can still come from an inaccurate forecast.

02

Confidence Needs Evidence

High confidence should be evaluated against forecast accuracy, not only final returns.

03

Python Can Structure Thinking

Coding helped convert investment reasoning into measurable decision-quality metrics.

Next step: Backtesting • Benchmarks • Risk-adjusted metrics
